Abstract

We present a mechanism for recovering consistent data from inconsistent set of assertions. For a common family of knowledge-bases we also provide an efficient algorithm for doing so automaticly. This method is nonmonotonic and paraconsistent. It is particularly useful for making diagnoses on faulty devices.

Subject areas: Knowledge-based systems, Non-standard logics for AI, Reasoning under uncertainty, Model-based diagnosis.

1. Introduction

It is well-known that the classical calculus allows only a trivial reasoning in the presence of inconsistency. This property is particularly problematic when the system under consideration is aimed to deal with conflicts. This is the case, for instance, with diagnostic systems that are supposed to analize the discrepancy between the actual behavior of some device and the way it is meant to behave. A common approach of handling inconsistent information is to consider some consistent subsets that still contain meaningful data. The usual method of doing so is to consider the maximal consistent subsets of the "polluted" data. The main drawback of this method is that none of these subsets necessarily correspond to the intended semantics of the original information. Even in the simplest inconsistent knowledgebase $KB = \{p, \neg p\}$ every maximal consistent subset of KBclassically contradicts an explicit data of KB. In the case of diagnostic systems this means that a diagnosis based on a maximal consistent subset might not truthfully describe the malfunctioning part of the examined device.

We propose here a different approach to "salvage" consistent data without contradicting any assertion of the original information. For a common family of knowledge-bases

we also provide an efficient algorithm for recovering this data. We then illustrate the ideas in a diagnostic system for checking faulty circuits. The underlying formalism is based on Belnap's four-valued logic [Be77a, Be77b], and it is shown to be nonmonotonic and paraconsistent [dC74].

Due to a lack of space most of the proofs are omitted; They will be given in the full version of the paper.

2. Preliminaries

We present a formalism that is based on Belnap's wellknown four-valued logic. For a detailed discussion on this logic see, e.g., [Be77a, Be77b]. We denote by t and fthe classical values. \perp and \top denote, respectively, lack of knowledge and "over"-knowledge (conflict). It is usual to consider these four values according to two partial orders: One, \leq_t , might intuitively be understood as reflecting differences in the "measure of truth" that every value represents. According to this order, f is the minimal element, t is the maximal one, and \perp , \top are two intermediate values that are incomparable. $(\{t, f, \top, \bot\}, \le_t)$ is a distributive lattice with an order reversing involution \neg , for which $\neg \top = \top$ and $\neg \bot = \bot$. We shall denote the meet and the join of this lattice by \wedge and \vee , respectively. The other partial order, \leq_k , is understood (again, intuitively) as reflecting differences in the amount of knowledge or information that each truth value exhibits. Again, $(\{t, f, \top, \bot\}, \le_k)$ is a lattice where \bot is its minimal element, \top – the maximal element, and t, f are incomparable.

The language we treat here is the standard propositional one. Given a set S of propositional formulae, we shall denote by $\mathcal{A}(S)$ the set of the atomic formulae that appear in the language S, and by $\mathcal{L}(S)$ the set of the literals that appear in some formula of S. The semantic notions are natural generalizations to the four-valued case of similar classical notions: A *valuation* ν is a function that assigns a truth value from $\{\top, \bot, t, f\}$ to each atomic formula. Any valuation is extended to complex formulae in the standard way.

We shall sometimes write $\psi:b\in\nu$ instead of $\nu(\psi)=b$. We will say that ν satisfies ψ , iff $\nu(\psi)\in\{t,\top\}$. t and \top are called *designated values*. A valuation that satisfies every formula in a given set of formulas, S, is said to be a *model* of S. The set of the models of S will be denoted mod(S). Note that unlike in the classical calculus, there are no tautologies here. In fact, excluded middle is not a valid rule in the four-valued case.

The formulae considered here are clauses, i.e.: disjuncts of literals. As the following lemma shows, representing the formulae in a clause form does not reduce the generality.

Lemma 2.1 For every formula ψ there is a finite set S of clauses such that for every valuation ν and for every $\phi \in S$, $\nu(\psi) \in \{\top, t\}$ iff $\nu(\phi) \in \{\top, t\}$.

Here is another useful property of clauses that will be used several times in the sequel:

Lemma 2.2 Let ψ be a clause, l_i $(i = 1 \dots n)$ – its literals, and ν – a valuation on $\mathcal{A}(\psi)$. Then $\nu(\psi) \in \{t, \top\}$ iff there is an $1 \le i \le n$ s.t. $\nu(l_i) \in \{t, \top\}$.

Definition 2.3 A knowledge-base KB is a pair (S, Exact), where S is a set of clauses, and Exact is a set of atoms in $\mathcal{A}(S)$ that are assumed to have only classical values. mod(KB) = mod(S, Exact) denotes the set of exact models of S, i.e.: the models of S in which every element of Exact is assigned a classical value. Formally: $mod(S, Exact) = \{M \in mod(S) \mid \forall p \in Exact \ M(p) \in \{t, f\}\}.$

Definition 2.4 Let $M \in mod(S)$. Define: $Inc_M(S) = \{p \in \mathcal{A}(S) \mid M(p) = \top\}.$

Definition 2.5 Let M, N be two exact models of a knowledge-base KB = (S, Exact).

- a) M is more consistent than N (notation: $M >_{con} N$), iff $Inc_M(S) \subset Inc_N(S)$.
- **b)** M is a *most consistent* exact model of KB (mcem, for short), if there is no other exact model of KB which is more consistent than M. The set of the most consistent exact models of KB will be denoted mcem(KB).
- c) M is smaller than N with respect to $\leq_k (M <_k N)$, if for any $p \in \mathcal{A}(S)$, $M(p) \leq_k N(p)$, and there is a $q \in \mathcal{A}(S)$ s.t $M(q) <_k N(q)$.
- **d)** M is a k-minimal model of a set S, if there is no other element of S which is smaller w.r.t. \leq_k than M.
- e) The set of the k-minimal models of mod(KB) will be denoted kmin(KB); the set of the k-minimal models of mcem(KB) (minimal mcems, for short) will be denoted $\Omega(KB)$.

Definition 2.6 Let KB = (S, Exact) be a knowledge-base, and ψ – a formula.

- a) $KB \models \psi$ if every exact model of KB is a model of ψ .
- **b)** $KB \models_{mcem} \psi$ if every meem of KB is a model of ψ .
- c) $KB \models_{k min} \psi$ if every k-minimal exact model of KB is a model of ψ .
- **d**) $KB \models_{\Omega} \psi$ if every k-minimal meem of KB is a model of ψ . ¹

Example 2.7 Let KB = (S, Exact) where $S = \{p, \neg p \lor \neg q, \neg q \lor r\}$ and $Exact = \emptyset$. The (exact) models of KB are listed in Figure 1 below (An asterisk denotes some value in $\{\bot, f, t, \top\}$)

Model No.	p	q	r	Model No.	p	q	r
M_1	t	f	\perp	M_9	T	L	t
M_2	t	f	t	M_{10}	Т	1	T
M_3	t	f	f	M_{11}	Т	t	t
M_4	t	f	T	M_{12}	Τ	t	Т
$M_5 \perp M_8$	t	\top	*	$M_{13} \perp M_{16}$	\top	f	*
				$M_{17}\perp M_{20}$	T	T	*

Figure 1. The exact models of KB

Here, $\operatorname{kmin}(KB) = \{M_1, M_9\}$, $\operatorname{mcem}(KB) = \{M_1, M_2, M_3\}$, and $\Omega(KB) = \{M_1\}$. Thus $KB \models_{mcem} \neg q$ and $KB \models_{\Omega} \neg q$, while $KB \not\models_{kmin} \neg q$ and $KB \not\models_{\neg q} q$. When $Exact = \{q\}$ the (minimal) meems of KB remain the same, while M_1 becomes the single k-minimal exact model of KB, so now $KB \models_{kmin} \neg q$.

Several consequence relations similar to \models_{mcem} are considered in the literature. Priest [Pr91] uses similar consequence relation for defining the logic LPm from the three-valued logic LP. Now, in [AA95] it is shown that for finite sets of assertions \models_{mcem} and \models_{Ω} are the same. Therefore, when switching to four valued semantics and using only the k-minimal mcems, one might consider fewer models than in the case of LPm, since for every k-minimal mcem that assigns \bot to an atomic formula p, there are two corresponding three-valued minimaly inconsistent LP models: One assigns t to p, and the other assigns it f. Also, here one might impose further constraints on the relevant models since we (unlike [Pr91]) do not consider models that are not exact.

Kifer and Lozinskii [KL92] also consider a similar relation in the framework of annotated logics. Like Priest, they also consider the most consistent models among *all* the possible models. They do not restrict the attention to some relevant subset (as we do) by constraining them in the meta-level. See [AA94, AA96] for further discussion and a comparison between \models_{mcem} and the consequence relation of [KL92].

¹One can view the consequence relation \models_{Ω} as a composition of the relations \models_{mcem} and \models_{kmin} . First we confine ourselves to the mcems of KB by using \models_{mcem} , then we minimize the valuations that we have got by using \models_{kmin} .

Definition 2.8 Let S be a set of assertions. An atom $p \in \mathcal{A}(S)$ is called a *positive* (*negative*) fact of S if $p \in S$ ($\neg p \in S$). p is called *strictly* positive (negative) fact if it is a positive (negative) fact and $\neg p \notin S$ ($p \notin S$).

Lemma 2.9 [AA95, Corollary 3.13] Let KB = (S, Exact). If p is a strictly positive fact of S then $KB \models_{mcem} p$ and $KB \not\models_{mcem} \neg p$. Strictly negative facts have the dual property.

A basic property of the knowledge-bases that we consider here is that for every exact model there is an meem which is at least as consistent. For finite knowledge-bases this is trivially the case. The following proposition assures that this property holds in *every* propositional knowledge-base:

Proposition 2.10 (Lin's Lemma, [Pr91]) Let KB be a (possibly infinite) set of clauses. For every exact model M of KB there is an mcem M' of KB s.t. $M' >_{con} M$. ²

3. Recovery of knowledge-bases

In this section we describe what we mean by saying "recovering an inconsistent knowledge-base". In particular we define and characterize the recovered parts of a knowledge-base. For that we first have to expand the notion of "consistency" to the four-valued case:

Definition 3.1 Let S be a set of clauses.

- a) A model M of S is consistent if $Inc_M(S) = \emptyset$.
- **b)** S is consistent if it has a consistent model.
- c) KB = (S, Exact) is *consistent* if S has a consistent exact model.

Lemma 3.2 S is consistent iff it is classically consistent.

Definition 3.3 A subset $S' \subseteq S$ is *consistent in* S w.r.t. Exact, if S' is a consistent set, and it has a consistent exact model that is expandable to an (not necessarily consistent) exact model of S.

Example 3.4 $S' = \{p\}$ is a consistent set, but it is *not* consistent in $S = \{p, \neg p\}$ w.r.t. any set Exact, since there is no consistent model of S' that is expandable to a model of S. Similarly, $S' = \{p\}$ is consistent in $S = \{p, \neg p \lor q, \neg p \lor \neg q\}$ w.r.t. $Exact = \{p\}$, but it is not consistent in S w.r.t. $Exact = \{q\}$, since there is no *consistent* exact model of S' that is expandable to an *exact* model of S.

Now we can define what we mean by recovering an inconsistent knowledge-base: **Definition 3.5** A recovered set of a knowledge-base (S, Exact) is a subset of S that is consistent in S w.r.t. Exact.

Example 3.6 Consider the knowledge-base $KB = (S, \{r, u\})$ where $S = \{p, p \lor q, \neg p \lor \neg r, r \lor \neg u, r \lor \neg v, u \lor v\}$. $KB' = \{p, p \lor q, \neg p \lor \neg r, r \lor \neg u\}$ is a recovered set of KB, since $\{p:t, q:\bot, r:f, u:f\}$ is a consistent exact model of KB' that is expandable to $M = \{p:t, q:\bot, r:f, u:f, v:\top\}$, which is an exact model of KB.

We now provide a method for practically recovering a knowledge-base. This method is strongly related to finding meems for *KB*. (see Proposition 3.10 below).

Definition 3.7 Let M be an exact model of a knowledge-base KB = (S, Exact). The set that is *associated with* M is: $KB_M = \{ \psi \in S \mid \mathcal{A}(\psi) \cap Inc_M(S) = \emptyset \}$.

Example 3.8 In Example 3.6, M is an exact model of KB, and $KB_M = KB'$.

Proposition 3.9 Every set that is associated with some exact model M of KB is a recovered set of KB.

Proposition 3.10 Every maximal recovered set of a knowledge-base KB is associated with some mcem M of KB.

4. Stratified knowledge-bases and their recovered sets

In general, computing meems for a given knowledge-base and discovering its recovered sets might not be an easy task. Even in relatively simple cases, where e.g. S is consistent and $Exact = \mathcal{A}(S)$, finding a recovered set for (S, Exact) reduces to the problem of logical satisfaction, since in this case one has to provide a classical model for S. Therefore, we confine ourselves to a special (nevertheless common) family of knowledge-bases, for which we provide an efficient algorithm that computes recoverable sets.

Definition 4.1 Let S be a set of formulae. S_{ν} — the *dilution* of S w.r.t. a partial valuation ν — is constructed from S by the following transformations:

- 1. Deleting every $\psi \in KB$ s.t. $\nu(\psi) \in \{t, \top\}$,
- 2. Removing from what is left every occurrence of a literal l such that $\nu(l) \in \{f, \bot\}$.

²This lemma is proved in [Pr91] for the three-valued case, and under the implicit assumption that $Exact = \emptyset$. However, it is easy to prove this lemma in our case as well.

³Note the similarity between the the dilution process and the Gelfond–Lifschitz transformation [GL88] used for providing semantics to logic programs with negations.

Definition 4.2 A set of formulae S is called *stratified*, if there is a set of "stratifications" $S_0 = S$, $S_1, \ldots, S_n = \emptyset$, so that for every $0 < i < n \perp 1$ there is a $p \in \mathcal{A}(S_i)$ s.t.:

- a) p is either a positive fact or a negative fact of S_i .
- b) S_{i+1} is a dilution of S_i w.r.t. the partial valuation p:t if p is a strictly positive fact of S_i , p:f if p is a strictly negative fact of S_i , and $p: \top$ if p is both a positive and a negative fact of S_i .

A knowledge-base KB = (S, Exact) is stratified iff S is stratified. In all the examples given here (see especially the one of Section 5), as well as in most of the known puzzles of the literature, the involved knowledge-bases are stratified.

Definition 4.3

- a) Let S be a set of formulae and $Exact \subseteq \mathcal{A}(S)$. A stratification $S_0 \ldots S_n$ of S is *proper* with respect to Exact if there is no $p \in Exact$ and an index $1 \le i \le n$ s.t. p is both a positive and a negative fact of S_i .
- **b)** A knowledge-base KB = (S, Exact) is called *properly stratified* iff there is a stratification of S that is proper w.r.t. Exact.

Example 4.4 Suppose that $KB = (S, \{r, u\})$ is the same knowledge-base of Examples 3.6 and 3.8. A possible stratification of S is $S_0 = \{p, p \lor q, \neg p \lor \neg r, r \lor \neg u, r \lor \neg v, u \lor v\}$, $S_1 = \{\neg r, r \lor \neg u, r \lor \neg v, u \lor v\}$, $S_2 = \{\neg u, \neg v, u \lor v\}$, $S_3 = \{\neg v, v\}$, $S_4 = \emptyset$. This stratification is proper.

The algorithm given in Figure 2 checks whether a given knowledge-base (S, Exact) is properly stratified. If so, it produces proper stratifications, and allows to construct recovered sets by providing corresponding (minimal) meems of (S, Exact) (see Theorem 4.7 below).

Every valuation ν produced by the algorithm of Figure 2 is determined by a sequence of the picked atomic formulae $\{p_0, p_1, \ldots, p_n\}$ of the calls to RECOVER. For shortening notations we shall just write ν when referring to an arbitrary valuation produced by the algorithm, instead of $\nu(p_0, p_1, \ldots, p_n)$.

Note: It is possible to assign any other truth value to the atoms that are assigned \bot (during the "filling" process of the algorithm), and still ν would be an exact model of KB. But in such cases, ν cannot be minimal w.r.t. \le_k . In particular, if the filling value is \top , then ν cannot be an mode of KB (see the proof of Theorem 4.7a). Also, it is possible to assign f to the elements of Exact that are assigned t during the filling process without losing any of the properties discussed below.

Example 4.5 In our canonical example (3.6, 3.8, and 4.4), where $S = \{p, p \lor q, \neg p \lor \neg r, r \lor \neg u, r \lor \neg v, u \lor v\}$ and

```
input: a knowledge-base KB = (S, Exact)
call RECOVER(S, \emptyset, 0)
procedure RECOVER(S, \nu, i)
/* S – the i-th stratification level of KB.
    \nu – the valuation constructed so far. */
    if (S = \emptyset) output \nu and return; /* \nu \in \Omega(KB) */
    positives := \{p \in \mathcal{A}(S) \mid p \in S\};
    negatives := \{p \in \mathcal{A}(S) \mid \neg p \in S\};
    if (positives = \emptyset \land \text{negatives} = \emptyset)
                     /* don't continue; KB is not stratified */
    if (\exists p \in \text{positives} \cap \text{negatives} \cap Exact)
        return; /* backtracking; not a proper stratification */
    while (\exists p \in \text{positives} \setminus \text{negatives}) {
        pick such a p;
        positives := positives \{p\};
        \nu := \nu \cup \{p:t\};
        S_{i+1} := S_{p:t}; \quad /* \text{ dilution } */
        for exery q \neq p s.t. q \in \mathcal{A}(S) \setminus \mathcal{A}(S_{i+1}) /* filling */
           if (q \notin Exact) \ \nu := \nu \cup \{q : \bot\} \text{ else } \nu := \nu \cup \{q : t\};
        RECOVER(S_{i+1}, \nu, i+1);
    while (\exists p \in \text{negatives} \setminus \text{positives}) {
        pick such a p;
        negatives := negatives \setminus \{p\};
        \nu := \nu \cup \{p:f\};
        S_{i+1} := S_{p:f}; \quad /* \text{ dilution } */
        for every q \neq p s.t. q \in \mathcal{A}(S) \setminus \mathcal{A}(S_{i+1}) /* filling */
           if (q \notin Exact) \nu := \nu \cup \{q : \bot\} \text{ else } \nu := \nu \cup \{q : t\};
        RECOVER(S_{i+1}, \nu, i+1);
    while (\exists p \in \text{positives} \cap \text{negatives}, p \notin Exact) {
        pick such a p;
        positives := positives \setminus \{p\};
        negatives := negatives \setminus \{p\};
        \nu := \nu \cup \{p : \top\};
        S_{i+1} := S_{p:\top}; \quad /* \text{ dilution } */
        for every q \neq p s.t. q \in \mathcal{A}(S) \setminus \mathcal{A}(S_{i+1}) /* filling */
           if (q \notin Exact) \nu := \nu \cup \{q : \bot\} else \nu := \nu \cup \{q : t\};
        RECOVER(S_{i+1}, \nu, i+1);
}
```

Figure 2. An algorithm for recovering stratified knowledge-bases

 $Exact = \{r, u\}$, the algorithm produces a single (minimal) meem of KB: $\nu(p) = t$, $\nu(q) = \bot$, $\nu(r) = f$, $\nu(u) = f$, and $\nu(v) = \top$. Figure 3 illustrates the processing of the algorithm in this case.

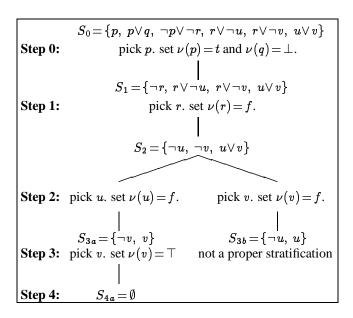

Figure 3. Generation of minimal meems and recovered sets for $\it KB$

Note that the algorithm does not necessarily produce every meem of the knowledge-base. In the last example such an meem is, for instance, $\{p: \top, q: \bot, r:t, u:t, v: \bot\}$. However, as Theorems 4.7 and 4.8 show, if KB is properly stratified the algorithm always finds at least one (minimal) meem, and it provides a maximal recovered set for KB.

We now consider some properties of the algorithm.

Proposition 4.6 Let KB = (S, Exact) be a finite knowledge-base. If it is properly stratified then the algorithm of Figure 2 finds every proper stratification of KB and outputs corresponding well-defined valuations for $\mathcal{A}(S)$. The algorithm halts without giving any valuation iff either KB is not stratified, or every stratification of S is not proper w.r.t. Exact.

It follows from Proposition 4.6 that the algorithm halts with a valuation for a finite KB iff KB is properly stratified. For the rest of this section suppose, then, that KB is a finite knowledge-base that is properly stratified.

Theorem 4.7 Let ν be a valuation produced by the algorithm for a knowledge-base KB. Then: (a) $\nu \in \operatorname{mcem}(KB)$, (b) $\nu \in \operatorname{kmin}(KB)$, and (c) $\nu \in \Omega(KB)$.

Proof: It is easy to see that every valuation ν produced by the algorithm is an exact model of KB. We show that ν is also most consistent among the exact models by an induction on the number of the recursive steps (n) that are required for creating it. If n=0 then $S_1=\emptyset$, so there is only the initial step in which ν might assign \top only to a literal l that is both a positive and a negative fact of S. Since in this case l is assigned \top by every model of S, ν must be most consistent. Suppose now that it takes $n \ge 1$ recursive steps to create ν . Denote by ν_i the part of the valuation ν that is determined during step i. Then:

$$(1): \ \, \mathit{Inc}_{\nu}(S) = \bigcup_{0 \leq i \leq n} \mathit{Inc}_{\nu_{i}}(S_{i}) = \mathit{Inc}_{\nu_{0}}(S) \cup \mathit{Inc}_{\nu'}(S_{1})$$

where $\nu' = \bigcup_{\substack{1 \leq i \leq n \\ \text{suppose that } M_1 \text{ is the reduction of } M \text{ to } S_1.}} \nu_i$. Now, let M be any meem of KB, and

(2): $Inc_M(S) - \{ p \in A(S) \setminus A(S_1) \mid M(p) - 1 \}$

$$(2): \quad Inc_{M}(S) = \{p \in \mathcal{A}(S) \setminus \mathcal{A}(S_{1}) \mid M(p) = \top\} \cup \{p \in \mathcal{A}(S_{1}) \mid M(p) = \top\} \cup \{p \in \mathcal{A}(S) \setminus \mathcal{A}(S_{1}) \mid M(p) = \top\} \cup Inc_{M_{1}}(S_{1})$$

By its definition, ν_0 might assign \top only to $l \in \mathcal{L}(S)$ s.t. $l, \overline{l} \in S$. Obviously, such an l must be assigned \top by every model of S, in particular $M(l) = \top$. Thus:

$$(3): \quad Inc_{\nu_0}(S) \subseteq \{p \in \mathcal{A}(S) \setminus \mathcal{A}(S_1) \mid M(p) = \top\}$$

• Suppose first that M_1 is an exact model of S_1 . Since the creation of ν' requires only $n \perp 1$ steps, then by the induction hypothesis ν' is an meem of S_1 . In particular, either $Inc_{\nu'}(S_1)$ and $Inc_{M_1}(S_1)$ are incomparable w.r.t. the containment relation, or else:

$$(4): \quad Inc_{\nu'}(S_1) \subset Inc_{M_1}(S_1)$$

From (1) – (4), either $Inc_{\nu}(S)$ and $Inc_{M}(S)$ are incomparable, or $Inc_{\nu}(S) \subseteq Inc_{M}(S)$, hence ν is an meem of KB.

• If M_1 is not an exact model of S_1 then M_1 is cannot be a model of S_1 either, since it is a reduction of an exact model (M) of S. Thus there is a $\psi_1 \in S_1$ s.t. $M_1(\psi_1) \notin \{t, \top\}$. Since *M* is a model of *S*, then by Lemma 2.2 there is a $\psi \in$ S and $l \in \mathcal{L}(\psi)$ s.t. $M(l) \in \{t, \top\}$, and $\{l\} \cup \mathcal{L}(\psi_1) \subset \mathcal{L}(\psi)$. Obviously, $l \in \mathcal{A}(S) \setminus \mathcal{A}(S_1)$. But then $\nu_0(l) \notin \{t, \top\}$ (otherwise ψ is eliminated in the dilution of S, and so $\psi_1 \notin S_1$). Moreover, $\nu_0(\bar{l}) \in \{t, \top\}$, since if $\nu_0(\bar{l}) \notin \{t, \top\}$ then necessarily $\nu_0(l) = \bot$, and this happens only if there is a literal $l' \in \mathcal{L}(\psi)$ s.t. $\nu_0(l')$ is designated, and in this case again, ψ is eliminated in the dilution of S, i.e. $\psi_1 \notin S_1$. Therefore, $\nu_0(l) \notin \{t, \top\}$ and $\nu_0(\overline{l}) \in \{t, \top\}$, so $\nu_0(l) = f$. l is not assigned this value in the filling process, since again, this would imply that ψ is eliminated in the dilution of S, and so $\psi_1 \not\in S_1$. Thus, by the definition of ν_0 and since S is stratified, necessarily $\bar{l} \in S$ and $l \notin S$. Hence $KB \models \bar{l}$. But M is an exact model of KB and so $M(\bar{l}) \in \{t, \top\}$. Since

we have shown that $M(l) \in \{t, \top\}$ as well, it follows that $M(l) = \top$ while $\nu(l) = f$. Therefore $Inc_M(S) \not\subseteq Inc_{\nu}(S)$. This completes the proof of part (a).

The proof of part (b) is by an induction on the number of recursive steps required to create ν , and is similar to that of part (a). Part (c) now follows from (a) and (b).

Theorem 4.8 Let ν be a valuation produced by the algorithm for KB. Then KB_{ν} is a maximal recovered set of KB.

Example 4.9 Consider again Example 4.5 and Figure 3. $KB_{\nu} = \{p, p \lor q, \neg p \lor \neg r, r \lor \neg u\}$ is a maximal recovered set of KB.

Proof of Theorem 4.8 (outlines): By Proposition 3.9 and Theorem 4.7, KB_{ν} is a recovered set of KB. If it is not a maximal recovered set, then by Proposition 3.10 there is an mode M of KB s.t. $KB_{\nu} \subset KB_{M}$. Since ν is also an mode of KB (Theorem 4.7 again), then there is a $p \in \mathcal{A}(S)$ s.t. $\nu(p) \neq \top$ while $M(p) = \top$. In particular, $p \notin Exact$, and by the construction of ν , either p or $\neg p$ is a strict fact of some stratification level S_{k} of S. Therefore there is some $\phi \in S$ s.t. $p \in \mathcal{A}(\phi)$ and $\mathcal{A}(\phi) \cap Inc_{\nu}(S) = \emptyset$ (Otherwise ϕ is diluted in some stage before stage k). Thus $\phi \in KB_{\nu}$ while $\phi \notin KB_{M}$, and so $KB_{\nu} \not\subset KB_{M}$.

Finally, let's consider some complexity issues. As we have noted before, the problem of recovering arbitrary knowledge-base is at least NP-complete. Denote by $O(A^B)$ that it takes O(A) running time to solve a certain problem when quering an oracle for solving problems with complexity O(B). Then our algorithm requires $O(|S|^{|A(S)|})$ running time to recover a knowledge-base (S, Exact) that is properly stratified.⁴ As the following proposition shows, the complexity of the algorithm is considerably reduced in cases that stratification implies proper stratification:

Proposition 4.10 Whenever every stratification of KB = (S, Exact) is proper, it takes $O(|S| \cdot |\mathcal{A}(S)|)$ running time to check whether KB is stratified, and if so, this is also the time needed to recover it (i.e., to provide a maximal recovered set of KB).

Obvious cases in which the condition of the last proposition is met are when $Exact = \emptyset$, or if there is no $l \in Exact$ s.t. both $l \in \mathcal{L}(S)$ and $\overline{l} \in \mathcal{L}(S)$.

5. Model-based diagnosis

Suppose that one is given a description of some system (physical device, for example) together with an observation

of its behaviour. Suppose further that this observation conflicts with the way the system is meant to behave. The obvious goal is to identify the components of the system that behave abnormally, so that the discrepancy between the observed and the correct system behavior would be explained. In such case it seems reasonable to assume that some minimal number of components are faulty. Therefore, the meems and their corresponding recovered sets are good candidates for providing accurate diagnoses, especially since they minimize the set of components that are assumed to behave differently than expected.

For dealing with these kind of problems, it is convenient first to expand the discussion to first-order logic. It is possible to do so in a straightforward way, provided that there are no quantifiers within the clauses; each clause that contains variables is considered as universally quantified. Consequently, a knowledge-base containing non-grounded formula, ψ , will be viewed as representing the corresponding set of ground formulae formed by substituting each variable that appears in ψ with every possible member of the Herbrand universe, $U^{.5}$ Formally: $KB^U = (S^U, Exact)$, where $S^U = \{ \rho(\psi) \mid \psi \in S, \ \rho : var(\psi) \to U \}, \ \rho \text{ is a } ground$ substitution from the variables of every $\psi \in KB$ to the individuals of U, and Exact consists of predicates that every instansiation of which should be assigned classical values. The exact models are the elements of $mod(S^U, Exact) =$ $\{M \in mod(S^U) \mid orall p \in Exact \ orall x_i \in U \ M\left(p(x_1,\ldots,x_n)
ight) \in$ $\{t,f\}\}$. KB^{U} is called the Herbrand expansion of KBw.r.t. Herbrand universe U.

Example 5.1 Figure 4 depicts a binary full adder, examined extensively in the literature of diagnostic systems (See, e.g., [Ge84, Re87, Gi88, Ra92] and many others). It consists of five components: two and-gates A_1 and A_2 , two xor-gates X_1 and X_2 , and an or-gate O_1 .

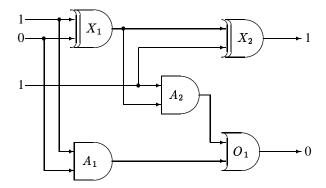

Figure 4. A full adder

⁴In our case at every stratification level the oracle chooses a fact that yields, eventually, to a proper stratification.

⁵In fact, this restriction guarantees that we stay, essentially, on a propositional level.

The full adder's description is given by system FA. It appears in Figure 5.

```
andGate(x) \wedge ok(x) 
ightarrow (out(x) \leftrightarrow (in1(x) \wedge in2(x))), \ xorGate(x) \wedge ok(x) 
ightarrow (out(x) \leftrightarrow (in1(x) \oplus in2(x))), \ orGate(x) \wedge ok(x) 
ightarrow (out(x) \leftrightarrow (in1(x) \vee in2(x))), \ andGate(x) 
ightarrow (\neg orGate(x) \wedge \neg xorGate(x)), \ xorGate(x) 
ightarrow (\neg andGate(x) \wedge \neg xorGate(x)), \ orGate(x) 
ightarrow (\neg andGate(x) \wedge \neg xorGate(x)), \ in1(X_1) \leftrightarrow in1(A_1), \ in2(X_1) \leftrightarrow in2(A_1), \ in1(A_2) \leftrightarrow in2(X_2), \ out(X_1) \leftrightarrow in2(X_2), \ out(X_1) \leftrightarrow in2(A_2), \ out(X_1) \leftrightarrow in1(O_1), \ andGate(A_1), \ andGate(A_2), \ xorGate(X_1), \ xorGate(X_2), \ orGate(O_2), \ ok(A_1), \ ok(A_2), \ ok(X_1), \ ok(X_2), \ ok(O_1), \ in1(X_1), \ \neg in2(X_1), \ in1(A_2), \ out(X_2), \ \neg out(O_1)
```

Figure 5. The system FA

Notice that the observation indicates that the physical circuit is faulty; both circuit outputs are wrong for the given inputs.

The predicates in1(x), in2(x), and out(x) are assigned values that correspond to binary values of the wires of the system. Therefore they should have only classical values (e.g., $in(G) = \top$ for a gate G is a meaningless value). Also, it seems natural to restrict the values of the predicates andGate, orGate, and xorGate to be only classical as well. This is because we know in advance what is the kind of each gate G in the system, and so the only open question about G is whether it behaves as expected (i.e., whether ok(G)). So, the actual knowledge-base for the full adder is (FA, Exact), where $Exact = \{in1, in2, out, andGate, orGate, xorGate\}$.

The table of Figure 6 lists the elements of mcm(FA, Exact). We have omitted from the table predicates (like $in1(X_1)$) that have the same (obvious) value in every exact model of (FA, Exact), and predicates that have the same values as some other predicates (like $in2(A_2)$, which is identical to $in1(X_2)$).

The mcems of (FA, Exact), and the recovered sets that are associated with them preserve what Reiter [Re87] calls the principle of parsimony; they represent the conjecture that some minimal set of components are faulty. For example, according to M1 the only component that behaves incorrectly is the xor gate X_1 . The recovered set that is associated with M1 reflects this indication: $FA_{M1} = \frac{1}{2} \frac{$

	$egin{array}{c} in1 \ X2 \end{array}$	$in1 \\ O1$	$in2 \\ O1$	ok $A1$	ok $A2$	ok $X1$	ok $X2$	ok O 1
M1	f	f	f	t	t	T	t	t
M2	t	f	f	t	T	t	T	t
M3	t	t	f	t	t	t	Т	T

Figure 6. The meems of (FA, Exact)

$$FA \setminus \{ok(X_1), \ xorGate(X_1) \wedge ok(X_1) \rightarrow (out(X_1) \leftrightarrow (in1(X_1) \oplus in2(X_1)))\}.$$

In particular, FA_{M_1} entails (w.r.t. both \models and \models_{mcem}) ok(x) for $x \in \{A_1, A_2, X_2, O_1\}$, but it does *not* entail $ok(X_1)$. Similarly, the other two meems M2 and M3, as well as their associated sets represent respective situations, in which gates $\{X_2, A_2\}$ and gates $\{X_2, O_1\}$ are faulties. These are the generally accepted diagnoses of this specific case (see, e.g. [Re87, Example 2.2], [Gi88, Sections 15,16], and [Ra92, Examples 1,4]).

One might treat FA_{M1} as the preferred recovered set, since it is the only set that entails that only a single component is faulty, and one normally expects components to fail independently of each other. This kind of diagnosis is known as a *single fault diagnosis*.

Next we show that the correspondence in the previous example between the fault diagnoses and the inconsistent assignments of the meems is not accidental. First we present two basic notions from the literature on model-based diagnosis:

Definition 5.2 [Re87] A *system* is a triple (*Sd*, *Comps*, *Obs*), where:

- a) Sd (system description) is a set of first order sentences.
- b) Comps (system components) is a finite set of constants.
- c) Obs (observations) is a finite set of sentences.

Definition 5.3 [Re87] A *diagnosis* is a minimal set $\Delta \subseteq Comps$ s.t. $Sd \cup Obs \cup \{ok(c) \mid c \in Comps \setminus \Delta\} \cup \{\neg ok(c) \mid c \in \Delta\}$ is classically consistent.

In the example above we assumed that the devices normally behave as expected. We next formalize this assumption:

Definition 5.4 A correct behaviour assumption for a given set of components $\Delta \subseteq Comps$ is the set $CBA(\Delta) = \{ok(c) \mid c \in \Delta\}$.

Notation 5.5 For a given system (Sd, Comps, Obs), and a set of components $\Delta \subseteq Comps$, denote $S(\Delta) = Sd \cup Obs \cup CBA(\Delta)$. Whenever $\Delta = Comps$ we shall write just S instead of S(Comps). Also, in the sequel we shall continue to assume that $S(\Delta)$ is a set of clauses. Recall that this assumption can be taken without any loss of generality.

Proposition 5.6 Denote by \models_{cl} the consequence relation of the first order classical logic.

- a) [Re87, Proposition 3.4] $\Delta \subseteq Comps$ is a diagnosis for (Sd, Comps, Obs) iff Δ is a minimal set such that $S(Comps \setminus \Delta)$ is classically consistent.
- **b)** [Re87, Proposition 3.3] If Δ is a diagnosis for (Sd, Comps, Obs) then $S(Comps \setminus \Delta) \models_{cl} \neg ok(c)$ for each $c \in \Delta$.

When considering diagnostic systems in the classical, two-valued logics, any inconsistency in the data causes trivial reasoning. This is, of course, not the case in the present treatment, where we allow truth value that exhibits inconsistencies, and only a subset of the atomic formulae necessarily have classical values. In terms of our discussion, then, a diagnostic system is a knowledge-base KB = (S, Exact), where $S = Sd \cup Obs \cup CBA(Comps)$.

Theorem 5.7 Let (S, Exact) be a knowledge-base of a diagnostic system, and suppose that the Herbrand base of S is $\{p(x_1, \ldots, x_n) \mid p \in Exact, x_i \in Comps\} \cup CBA(Comps)$. An exact model M of (S, Exact) is an meem of (S, Exact) iff $Inc_M(S) = CBA(\Delta)$ for some diagnosis Δ of S.

Outline of proof: (\Leftarrow) Otherwise there is an exact model M' s.t. $Inc_{M'}(S) \subset Inc_M(S) = CBA(\Delta)$, i.e.: there is a $c_0 \in \Delta$ s.t. $M'(ok(c_0)) \neq \top$. But: (a) $ok(c_0) \in S$ thus $M'(ok(c_0)) \in \{t, \top\}$, and: (b) $S(Comps \setminus \Delta) \models_{cl} \neg ok(c_0)$ and by Lemma 4.11 of $[AA96]^7$, $S(Comps \setminus \Delta) \models_{mcem} \neg ok(c_0)$, therefore $M'(\neg ok(c_0)) \in \{t, \top\}$. By (a) and (b), $M'(ok(c_0)) = \top$ – a contradiction.

 (\Rightarrow) By Proposition 5.6, in order to prove that Δ is a diagnosis for S it is sufficient to show that Δ is a minimal set such that $S(Comps \setminus \Delta)$ is classically consistent. This follows from the condition on Herbrand base of S that assures that for every exact model M of (S, Exact), $Inc_M(S) \subset CBA(Comps)$.

Corollary 5.8 Under the assumption of Theorem 5.7, if Δ is a diagnosis of S then there exists an mcem M of (S, Exact) s.t. $Inc_M(S) = CBA(\Delta)$.

It follows that whenever the requirement of Theorem 5.7 is met and (S, Exact) is properly stratified, one can use the algorithm of Section 4 for finding diagnoses and constructing maximal recovered knowledge-bases of the faulty system. This is the case, e.g., in Example 5.1.

6. Conclusion

We have proposed a mechanism for recovering consistent data from inconsistent set of assertions. Our approach

considers the contradictory data as useless, and regards all the remaining information unaffected. This kind of approach is nonmonotonic and paraconsistent in nature. For a common family of knowledge-bases we have also provided an efficient algorithm for an automatic recovery. Our method is particularly useful for diagnostics systems, where it might be used for supplying a description of the well-behaved parts of a faulty device.

⁶Note that this requirement is met in Example 5.1.

⁷According to that lemma, if S is a classically consistent set of assertions, ψ is a clause that does not contain any pair of an atomic formula and its negation, and ψ follows classically from S, then $S \models_{mcem} \psi$.
